## 1. BLE SDK 概述

GD32VW553 系列芯片是以 RISC-V 为内核的 32 位微控制器(MCU),包含了 Wi-Fi4/ Wi-Fi6 及 BLE5.3 连接技术。GD32VW553 Wi-Fi+BLE SDK 集成 Wi-Fi 驱动、BLE 驱动、LwP TCP/IP 协议栈、MbedTLS 等组件,可使开发者基于 GD32VW553 快速开发物联网应用程序。本应用指南描述了 BLE 软件框架及相关 API 接口,旨在帮助开发者熟悉并使用 BLE API 开发自己的应用程序,Wi-Fi 相关内容请参考《AN158 GD32VW553 Wi-Fi 开发指南》。

## 1.1. BLE 软件框架

#### 图 1-1. BLE 软件框架图

## **BLE STACK**

如 <u>图 1-1. BLE 软件框架图</u>所示,GD32VW553 BLE 软件部分由 BLE STACK、BLE COMPONENTS、BLE services 和 BLEAPP 四个模块组成。

BLE STACK 是对 BLE 协议栈的实现,包含了 GAP、GATT、SMP、L2CAP、HCI 和 LL 等模块。BLE STACK 运行于一个单独的 task,与 BLE COMPONENTS 间通过 TASK message 进行交互,APP 需要通过 BLE COMPONENTS 对 STACK 进行操作。

BLE COMPONENTS 由多个组件构成,和 BLE service、BLE APP 运行在同一个 task,为 APP 提供对 STACK 的控制和状态通知等接口。需要注意的是,BLE 的大部分操作都是异步执行的,APP 需要向各个模块中注册 callback 处理函数,BLE COMPONENTS 会在 callback 函数中通知 APP 调用 API 的执行结果或者上报对端发起的操作请求等内容。各组件之间相互独立,APP 可根据需要选择不同的组件对其进行初始化并注册对应的 callback 函数。

BLE ADAPTER 模块主要提供对本地 BLE 相关属性进行配置和获取等操作的接口,<u>BLE</u> adapter API 介绍了 ADAPTER 模块的 API 使用。

BLE ADV 模块主要提供创建/删除 advertising set,开启/停止发送 advertising packets 等操作的接口,*BLE advertising API*介绍了 ADV 模块的 API 使用,*BLE advertising data API*提供了一些在 advertising data 中查找特定的 AD type 数据的接口。

BLE SCAN 模块主要提供搜索 advertising set 的接口并且将搜索的结果上报给 APP, BLE

scan API介绍了 SCAN 模块的 API 使用。

BLE CONNECTION 模块主要提供建立连线,获取对端设备信息,获取或设置连线参数等接口, BLE connection API 介绍了 CONNECTION 模块的 API 使用。

BLE SECURITY 模块主要提供 pairing,authentication,encryption 等过程中交互需要的接口, BLE security API 介绍了 SECURITY 模块的 API 使用。

BLE LIST 模块主要提供对 FAL,RAL,PAL 进行操作的接口,包括添加 device 到 list,删除 list 中的 device,清除 list 等,\_*BLE list API* 介绍了 LIST 模块的 API 使用。

BLE PERIODIC SYNC 模块主要提供同步 periodic advertising,上报接收到的 periodic advertising data 等接口, *BLE periodic sync API*介绍了 PERIODIC SYNC 模块的 API使用。

BLE STORAGE 模块使用 flash 来存储并管理 peer 的 bond 信息和 GATT 信息等,其中 bond 信息包括 peer\_irk, peer\_ltk, peer\_csrk, local\_irk, local\_itk 和 local\_csrk 等,<u>BLE storage API</u>介绍了 STORAGE 模块的 API 使用。

BLE GATT server 模块主要提供注册/删除 GATT service,向 GATT CLIENT 发送 notification/indication 等接口,<u>BLE gatts API</u>介绍了 GATT server 模块的 API 使用。

BLE GATT client 模块主要提供发起 GATT discovery,读写对端 GATT server 中的 attribute 等接口,*BLE gattc API*介绍了 GATT client 模块的 API 使用。

BLE services 是基于 GATT server、GATT client 模块实现的不同 service 及 profile,包括 BAS、DIS 等,用户也可以根据需要使用 GATT server、GATT client 接口实现私有 service 等。

BLE APP 层是多个应用的集合,例如 blue courier(蓝牙配网)及用户自定义应用等。APP 根据不同的需要可以向不同的模块注册 callback 函数处理相应的消息。

## 3. 应用举例

## 3.1. 扫描

BLE 扫描功能用于查找周围环境中的低功耗蓝牙设备。使能扫描功能后,将会把扫描到的设备上报至应用层。

该功能快速使用主要分以下几步:

1. 注册 event 处理函数,可处理扫描状态的变化和广播数据的上报。

#### 表 3-1. 扫描 event 处理函数示例代码

```
static void ble_app_scan_mgr_evt_handler(ble_scan_evt_t event, ble_scan_data_u *p_data)
    switch (event) {
    case BLE_SCAN_EVT_STATE_CHG:
        if (p_data->scan_state.scan_state == BLE_SCAN_STATE_ENABLED) {
            dbg_print(NOTICE, "Ble Scan enabled status 0x%x\r\n", p_data->scan state.reason);
        } else if (p data->scan state.scan state == BLE SCAN STATE ENABLING) {
            scan_mgr_clear_dev_list();
        } else if (p data->scan state.scan state == BLE SCAN STATE DISABLED) {
                                   "Ble
            dbg_print(NOTICE,
                                                     disabled
                                                                                  0x%x\r\n"
                                            Scan
                                                                       status
p data->scan state.reason);
        }
        break:
    case BLE_SCAN_EVT_ADV_RPT:
        scan_mgr_report_hdlr(p_data->p_adv_rpt);
        break:
   }
```

2. 通过 ble scan param set 配置扫描参数,结构体参数如下:

2. 通过 bie\_scan\_param\_set 配直扫描多数,结构体多数如下:
type---扫描类型,可设置为 general discovery(通用扫描)、limit discovery(限制扫描)等。
prop---扫描属性,可设置 1M 和 CODED PHY 的主动扫描或被动扫描以及 filter 策略等。
dup\_filt\_pol---重复过滤,使能后,不会把收到的广播信号重复上报至 application。
scan\_intv---扫描间隔,控制器间隔多长时间扫描一次。
scan\_win---扫描窗口,每一次扫描持续的时间。
duration---扫描时长,配置 0 表示持续扫描。
period---是否周期扫描,以 duration 为周期。

#### 表 3-2. 配置扫描参数示例代码

```
/**@brief Function for set scan parameters.
 * @param[in] param
                                  scan parameters (see enum #ble gap scan param t)
 * @retval BLE ERR NO ERROR
                                       If ble scan module disable successfully.
ble_status_t ble_scan_param_set(ble_gap_scan_param_t *p_param);
/** 默认的扫描参数如下*/
p ble scan env->param.type = BLE GAP SCAN TYPE GEN DISC;
p_ble_scan_env->param.prop = BLE_GAP_SCAN_PROP_PHY_1M_BIT |
                             BLE GAP SCAN PROP ACTIVE 1M BIT |
                             BLE GAP SCAN PROP PHY CODED BIT |
                             BLE_GAP_SCAN_PROP_ACTIVE_CODED_BIT;
p ble scan env->param.dup filt poI = BLE GAP DUP FILT EN;
p_ble_scan_env->param.scan_intv_1m = 160; // 100ms
p_ble_scan_env->param.scan_intv_coded = 160; // 100ms
p ble scan env->param.scan win 1m = 48; // 30ms
p ble scan env->param.scan win coded = 48; // 30ms
p ble scan env->param.duration = 0;
p ble scan env->param.period = 0;
```

3. 使能扫描,调用 ble scan enable API 即可开启扫描。

#### 表 3-3. 使能扫描示例代码

```
void app_scan_enable(bool update_rssi)
{
    if (ble_scan_enable() != BLE_ERR_NO_ERROR) {
        dbg_print(NOTICE, "app_scan_enable fail!\r\n");
        return;
    }
}
```

## 3.2. 广播

BLE 广播功能用于发送广播报文,可以让周围的低功耗蓝牙设备发现并连接或者发送周期性数据等。可配置为 legacy advertising(传统广播)、extened advertising(扩展广播)、periodic advertising(周期广播)。

该功能快速使用主要分以下几步:

1. 注册 event 处理函数,用来处理广播状态的变化、收到的扫描请求的上报。

#### 表 3-4. 广播 event 处理函数示例代码

```
static void app_adv_mgr_evt_hdlr(ble_adv_evt_t adv_evt, void *p_data, void *p_context)
```

```
{
    app_adv_actv_t *p_adv = (app_adv_actv_t *)p_context;
    switch (adv_evt) {
    case BLE_ADV_EVT_STATE_CHG: {
        ble adv state chg t *p chg = (ble adv state chg t *)p data;
        ble_adv_state_t old_state = p_adv->state;
        dbg print(NOTICE, "adv state change 0x%x ==> 0x%x, reason 0x%x\r\n", old state,
p chg->state, p chg->reason);
        p_adv->state = p_chg->state;
             ((p_chg->state
                                     BLE_ADV_STATE_CREATE)
                                                                    &&
                                                                           (old_state
BLE ADV STATE CREATING)) {
            p_adv->idx = p_chg->adv_idx;
            app_print("adv index %d\r\n", p_adv->idx);
            app_adv_start(p_adv);
        } else if ((p_chg->state == BLE_ADV_STATE_CREATE) &&
                                                                          (old state
BLE_ADV_STATE_START)) {
            dbg print(NOTICE, "adv stopped, remove %d\r\n", p adv->remove after stop);
            if (p adv->remove after stop) {
                ble_adv_remove(p_adv->idx);
                p_adv->remove_after_stop = false;
            }
        } else if (p_chg->state == BLE_ADV_STATE_IDLE) {
            free_adv_actv(p_adv);
       }
   } break;
    case BLE ADV EVT DATA UPDATE RSP: {
        ble_adv_data_update_rsp_t *p_rsp = (ble_adv_data_update_rsp_t *)p_data;
        dbg_print(NOTICE, "adv data update rsp, type %d, status 0x%x\r\n", p_rsp->type,
p rsp->status);
   } break;
    case BLE_ADV_EVT_SCAN_REQ_RCV: {
        ble_adv_scan_req_rcv_t *p_req = (ble_adv_scan_req_rcv_t *)p_data;
        dbg_print(NOTICE, "scan req rcv, device addr %02X:%02X:%02X:%02X:%02X:%02X\r\n",
               p_req->peer_addr.addr[5], p_req->peer_addr.addr[4], p_req->peer_addr.addr[3],
               p_req->peer_addr.addr[2], p_req->peer_addr.addr[1], p_req->peer_addr.addr[0]);
```

```
} break;

default:

break;

}
```

2. 设备打出广播报文主要分两步执行:创建广播和使能广播。在广播状态为创建成功后才 能使能广播。例如以下应用层创建广播代码,基于不同的广播类型配置不同的广播参数。

#### 表 3-5. 创建广播示例代码

```
ble_status_t app_adv_create(app_adv_param_t *p_param)
   app_adv_actv_t *p_adv;
   ble adv param t adv param = \{0\};
   p_adv = get_free_adv_actv();
   if (p adv == NULL) {
       return BLE_ERR_NO_RESOURCES;
   }
   p adv->max data len = p param->max data len;
   adv param.param.ow n addr type = p param->ow n addr type;
   if (p_param->type == BLE_ADV_TYPE_LEGACY) {
       adv param.param.type = BLE GAP ADV TYPE LEGACY;
       adv_param.param.prop = p_param->prop;
       if (p_param->w l_enable) {
           adv_param.param.filter_pol = BLE_GAP_ADV_ALLOW_SCAN_FAL_CON_FAL;
           adv_param.param.disc_mode = BLE_GAP_ADV_MODE_NON_DISC;
       } else {
           adv param.param.filter pol = BLE GAP ADV ALLOW SCAN ANY CON ANY;
           adv_param.param.disc_mode = p_param->disc_mode;
       }
       adv_param.param.ch_map = APP_ADV_CHMAP;
       adv_param.param.primary_phy = p_param->pri_phy;
   } else if (p param->type == BLE ADV TYPE EXTENDED) {
       adv_param.param.type = BLE_GAP_ADV_TYPE_EXTENDED;
       adv_param.param.prop = p_param->prop;
       if (p_param->w l_enable) {
           adv_param.param.filter_pol = BLE_GAP_ADV_ALLOW_SCAN_FAL_CON_FAL;
```

```
adv param.param.disc mode = BLE GAP ADV MODE NON DISC;
   } else {
        adv param.param.filter pol = BLE GAP ADV ALLOW SCAN ANY CON ANY;
       adv_param.param.disc_mode = p_param->disc_mode;
   }
    adv_param.param.ch_map = APP_ADV_CHMAP;
    adv param.param.primary phy = p param->pri phy;
    adv_param.param.adv_sid = get_adv_sid();
    adv param.param.max skip = 0x00;
    adv_param.param.secondary_phy = p_param->sec_phy;
    return BLE GAP ERR INVALID PARAM;
}
if (adv_param.param.prop & BLE_GAP_ADV_PROP_DIRECTED_BIT) {
    adv_param.param.peer_addr = p_param->peer_addr;
    adv param.param.disc mode = BLE GAP ADV MODE NON DISC;
    p_adv->peer_addr = p_param->peer_addr;
}
if (adv param.param.prop & BLE GAP ADV PROP ANONY MOUS BIT) {
    adv_param.param.disc_mode = BLE_GAP_ADV_MODE_NON_DISC;
}
p_adv->disc_mode = adv_param.param.disc_mode;
adv_param.param.adv_intv_min = APP_ADV INT MIN;
adv_param.param.adv_intv_max = APP_ADV_INT_MAX;
if (p_adv->disc_mode == BLE_GAP_ADV_MODE_LIM_DISC) {
    adv_param.param.duration = 1000;
                                         // 10s
}
if (p_param->type != BLE_ADV_TYPE_LEGACY) {
    adv_param.include_tx_pw r = true;
    adv param.scan req ntf = true;
}
return ble_adv_create(&adv_param, app_adv_mgr_evt_hdlr, p_adv);
```

3. 使能广播。在注册的 event 处理函数中收到创建广播成功的消息后就可调用 ble adv start 接口来使能广播。之后,在 event 处理函数中收到上报广播状态为

BLE ADV STATE START表示使能成功。

ble\_adv\_start API 中后三个参数分别用来设置广播数据,扫描响应数据和周期性广播数据,可由应用层来直接设置内容,也可通过配置参数由 BLE ADV 模块来封装。例如以下 code,所有数据内容都是直接由应用层来设置的。

#### 表 3-6. 使能广播示例代码

```
static uint8_t adv_data_1[7] = \{0x06, 0x16, 0x52, 0x18, 0x18, 0x36, 0x9A\};
static uint8 t per data 1[52] = \{0x33, 0x16, 0x51, 0x18, 0x40, 0x9c, 0x00, 0x01, 0x02, 0x06, 0x61, 0
                                                                                                              0x00, 0x00, 0x00, 0x00, 0x0d, 0x02, 0x01, 0x08, 0x02, 0x02,
                                                                                                               0x01, 0x03, 0x04, 0x78, 0x00, 0x02, 0x05, 0x01, 0x07, 0x03,

## 3.3. GATT server 应用

notification/indication 等功能,用户可根据需要实现特定的 service,具体 API 可以参考 <u>BLE gatts API</u>。下面以 DIS 为例说明如何使用这些 API 实现一个 service server,文件为 MSDK\ble\profile\dis\ble diss.c。

#### 3.3.1. service 添加

向 BLE GATT server 模块中添加 service 主要通过 ble\_gatts\_svc\_add 函数完成,该函数的输入参数包括 service UUID,service attribute database,GATT server 消息的 callback 处理函数等内容。Service UUID 可以为 16 bit,32 bit 或者 128bit 中的任意一种,需要在 info 参数中予以说明,如 ble diss 的 code,service UUID 使用的是 UUID 16,调用 ble\_gatts\_svc\_add 函数时就用 SVC UUID(16)进行说明。

#### 表 3-7. 添加 service 示例代码

```
ret = ble_gatts_svc_add(&ble_diss_svc_id, ble_dis_uuid, 0, SVC_UUID(16), ble_diss_attr_db,
BLE DIS HDL NB, ble diss srv cb);
```

#### 3.3.2. service attribute database

Service attribute database 是由一系列 ble\_gatt\_attr\_desc\_t 元素组成的数组,数组中的每一个元素就是一个 attribute,可以是 primary service,characteristic declaration,characteristic value declaration 等内容,用户可以根据不同 service 的需求进行自由组合。

每一个 attribute 由 UUID 和其属性说明组成,DIS 所有的 attribute 都是只读的,所以只需要指定 RD property 就可以,对于 characteristic value declaration,还可以指定 value 的最大 size。

#### 表 3-8. service database 示例代码

```
const ble_gatt_attr_desc_t ble_diss_attr_db[BLE_DIS_HDL_NB] =

{
     [BLE_DIS_HDL_SVC] = {UUID_16BIT_TO_A RRAY(BLE_GATT_DECL_PRIMA RY_SERVICE).}

PROP(RD), 0},

[BLE_DIS_HDL_MANUFACT_NAME_CHAR] =

{UUID_16BIT_TO_A RRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},

[BLE_DIS_HDL_MANUFACT_NAME_VAL] =

{UUID_16BIT_TO_A RRAY(BLE_DIS_CHAR_MANUF_NAME), PROP(RD),

BLE_DIS_VAL_MAX_LEN},

[BLE_DIS_HDL_MODEL_NB_CHAR] =

[BLE_DIS_HDL_MODEL_NB_VAL] =

{UUID_16BIT_TO_A RRAY(BLE_DIS_CHAR_MODEL_NB), PROP(RD),

BLE_DIS_VAL_MAX_LEN},

[BLE_DIS_VAL_MAX_LEN],

[BLE_DIS_HDL_SERIAL_NB_CHAR] =

{UUID_16BIT_TO_A RRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},
```

```
[BLE DIS HDL SERIAL NB VAL] =
{UUID_16BIT_TO_ARRAY(BLE_DIS_CHAR_SERIAL_NB), PROP(RD),
BLE DIS VAL MAX LEN},
    [BLE_DIS_HDL_HARD_REV_CHAR] =
{UUID 16BIT TO ARRAY(BLE GATT DECL CHARACTERISTIC), PROP(RD), 0},
    [BLE_DIS_HDL_HARD_REV_VAL] = {UUID_16BIT_TO_ARRAY(BLE_DIS_CHAR_HW_REV),
PROP(RD), BLE DIS VAL MAX LEN},
    [BLE DIS HDL FIRM REV CHAR] =
{UUID_16BIT_TO_ARRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},
    [BLE DIS HDL FIRM REV VAL] = { UUID 16BIT TO ARRAY(BLE DIS CHAR FW REV),
PROP(RD), BLE DIS VAL MAX LEN},
    [BLE DIS HDL SW REV CHAR] =
{UUID_16BIT_TO_ARRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},
    [BLE_DIS_HDL_SW_REV_VAL] = {UUID_16BIT_TO_ARRAY(BLE_DIS_CHAR_SW_REV),

    [BLE DIS HDL SYSTEM ID CHAR] =
{UUID 16BIT TO ARRAY(BLE GATT DECL CHARACTERISTIC), PROP(RD), 0},
    [BLE DIS HDL SYSTEM ID VAL] = {UUID 16BIT TO ARRAY(BLE DIS CHAR SYS ID),
PROP(RD), BLE_DIS_SYS_ID_LEN},
    [BLE_DIS_HDL_IEEE_CHAR] =
{UUID_16BIT_TO_ARRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},
    [BLE DIS HDL IEEE VAL] = {UUID 16BIT TO ARRAY(BLE DIS CHAR IEEE CERTIF),
PROP(RD), BLE_DIS_VAL_MAX_LEN},
    [BLE DIS HDL PNP ID CHAR] =
{UUID_16BIT_TO_ARRAY(BLE_GATT_DECL_CHARACTERISTIC), PROP(RD), 0},
   [BLE_DIS_HDL_PNP_ID_VAL] = {UUID_16BIT_TO_ARRAY(BLE_DIS_CHAR_PNP_ID),
PROP(RD), BLE DIS PNP ID LEN},
```

#### 3.3.3. service attribute 读写处理

ble\_gatts\_svc\_add 最后一个参数是注册一个 GATT server event callback 函数,当对端 client 对 该 service 进 行 read、write 操作时 就 会 执 行 该 callback 函数,消息类型为 BLE\_SRV\_EVT\_GATT\_OPERATION , subevent 为 BLE\_SRV\_EVT\_READ\_REQ 或 BLE\_SRV\_EVT\_WRITE\_REQ 。 subevent 数 据 类 型 为 ble\_gatts\_read\_req\_t 或 者 ble\_gatts\_write\_req\_t,其中有 att\_idx 参数表明当前操作对应的 attribute 在注册的 service attribute database 数组中对应的 index。

#### 表 3-9. attribute 读写函数示例代码

```
ble_status_t ble_diss_srv_cb(ble_gatts_msg_info_t *p_srv_msg_info)
    uint8_t attr_idx = 0;
    uint16_t len = 0;
    uint8 t attr len = 0;
    uint8_t *p_attr = NULL;
    if (p_srv_msg_info->srv_msg_type == BLE_SRV_EVT_GATT_OPERATION) {
        if (p srv msg info->msg data.gatts op info.gatts op sub evt ==
BLE_SRV_EVT_READ_REQ) {
            ble_gatts_read_req_t *p_read_req =
&p_srv_msg_info->msg_data.gatts_op_info.gatts_op_data.read_req;
            attr idx = p read req->att idx;
            switch(attr_idx){
            case BLE_DIS_HDL_MANUFACT_NAME_VAL: {
                         = ble diss val.manufact name;
                 attr_len = ble_diss_val.manufact_name_len;
            } break;
            case BLE DIS HDL MODEL NB VAL: {
                         = ble_diss_val.model_num;
                 attr len = ble diss val.model num len;
            } break;
            case BLE DIS HDL SERIAL NB VAL: {
                         = ble diss val.serial num;
                 attr_len = ble_diss_val.serial_num_len;
            } break;
            case BLE_DIS_HDL_HARD_REV_VAL: {
                         = ble diss val.hw rev;
                 attr_len = ble_diss_val.hw_rev_len;
            } break;
            case BLE_DIS_HDL_FIRM_REV_VAL: {
                         = ble_diss_val.fw_rev;
                 attr_len = ble_diss_val.fw_rev_len;
            } break;
            case BLE_DIS_HDL_SW_REV_VAL: {
                 p attr
                         = ble diss val.sw rev;
```

```
attr len = ble diss val.sw rev len;
        } break;
        case BLE_DIS_HDL_SYSTEM_ID_VAL: {
                     = ble_diss_val.sys_id;
             attr len = BLE DIS SYS ID LEN;
        } break;
        case BLE_DIS_HDL_IEEE_VAL: {
             p attr
                    = ble diss val.ieee data;
             attr_len = ble_diss_val.ieee_data_len;
        } break;
        case BLE_DIS_HDL_PNP_ID_VAL: {
                    = ble diss val.pnp id;
             attr_len = BLE_DIS_PNP_ID_LEN;
        } break;
        default:
             return BLE_ATT_ERR_INVALID_HANDLE;
        }
        if (p_read_req->offset > attr_len) {
             return BLE ATT ERR INVALID OFFSET;
        }
        len = ble_min(p_read_req->max_len, attr_len - p_read_req->offset);
        p_read_req->val_len = len;
        memcpy(p_read_req->p_val, p_attr, len);
    }
}
return BLE ERR NO ERROR;
```

如果 service 中有 attribute 支持 Client Characteristic Configuration declaration(CCCD), 在使能后,可调用 ble\_gatts\_ntf\_ind\_send 接口发送 notification/indication。

#### 表 3-10. 发送 notification 示例代码

```
static void bcw l_ntf_event_send(uint8_t *p_val, uint16_t len)
{

if (bcw l_env.ntf_cfg == 0) {

dbg_print(ERR, "%s fail\r\n", __func__);

return;
```

```
}
ble_gatts_ntf_ind_send(bcw1_env.conn_id, bcw1_env.prf_id, BCW_IDX_NTF, p_val, len, BLE_GATT_NOTIFY);
}
```

## 3.4. BLE 配网

Blue courier 是一项基于 BLE 的 WIFI 网络配置功能。通过协议将 WIFI 的 SSID、密码、信道、加密类型等传输到 GD 设备,基于这些信息,GD 设备可连接到 AP 或者建立 SoftAP。链路上支持数据的分片及 CRC16 完整性校验,安全上依赖 BLE 链路上的加密,其次对于涉及 SSID 和密码的消息传输,使用了编码方式避免空气中传输明文。使用参考《AN153 GD32VW553基本指令用户指南》的 ble courier wifi 命令。

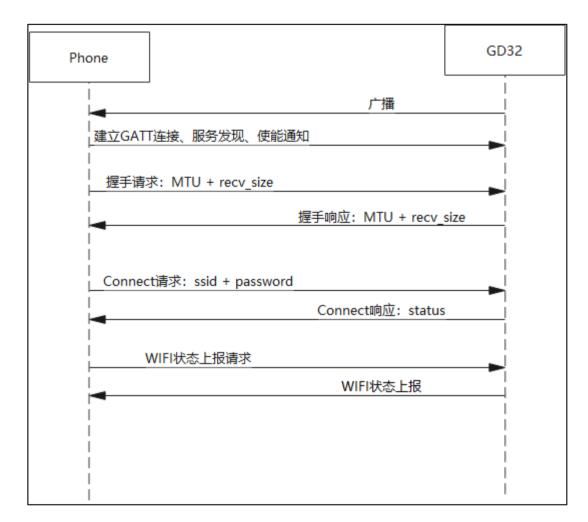

#### 3.4.1. Blue courier 流程

下面以配置 WIFI 作为 station 连接 AP 举例,介绍了广播、连接、服务发现、使能通知、握手、传输数据、回传连接状态等关键步骤。

- 1. GD 设备开启 Blue courier wifi 后,会向 GATT server 模块注册特定的 service,发送带有特定 advertising data 的广播。广播内容可以按需对其进行自定义。
- 2. 使用微信小程序搜索到该广播后,手机将作为 GATT Client 连接 GD 设备。
- 3. 成功建立 GATT 连接后,手机会向 GD 设备发送握手请求消息,GD 设备收到握手消息后将回复握手响应消息。
- 4. 手机可向 GD 设备发送连接 WIFI、创建 SoftAp、获取 WIFI 状态等消息。

#### 3.4.2. GATT 相关说明

配网 service 的添加可以参考 service 添加中的说明。

配网 service 使用的 UUID 说明见表 3-11. 配网 service UUID 错误!未找到引用源。。

#### 3.4.3. 广播数据

为了便于其他设备发现本地设备支持BLE配网功能,在广播数据中必须携带 Blue courier WIFI Service UUID,对端可以在搜索 BLE 设备时基于 Service UUID 进行过滤,具体内容见。

表 3-12. 广播数据中 service UUID 内容

#### 3.4.4. 帧格式

Blue courier 手机应用程序与 GD 设备之间的通信帧格式如下:
